

Final Validation:

Finding 1: Digital Channel Growth & Settled Volume

- **Original Finding:** Digital channels drive primary business growth based solely on high gross transaction volume.
- **Validation Method:** Executed SQL CTEs and window aggregations comparing Gross Transaction Volume against Net Settled Volume (excluding failed, reversed, and pending transactions).
- **Result:** While gross volume reached ₦560.48M, total failed (₦24.83M), reversed ₦15.63M), and pending ₦9.22M) transactions accounted for ₦49.68M (8.86%) in unsettled capital. Mobile App alone experienced 296 failed attempts worth ₦13.09M.
- **Conclusion (Revised): Needs Revision.** High gross digital volume conceals revenue leakage caused by switch drop-offs. Primary performance evaluation shifted from Gross Volume to Net Settled Revenue.

Finding 2: Customer Lifetime Value (CLV) & High-Frequency Users

- **Original Finding:** Customers with high transaction frequency automatically yield the highest Customer Lifetime Value (CLV).
- **Validation Method:** Applied SQL window ranking (NTILE, DENSE_RANK) and RFM (Recency, Frequency, Monetary) clustering cross-referenced with account status.
- **Result:** Several high-frequency transactors generated low monetary yield and exhibited high risk flag rates. Furthermore, 7.13% of registered accounts (107 users) were identified as completely dormant, while 8.87% of total customer accounts were classified as non-active.
- **Conclusion (Revised): Needs Revision.** Static frequency metrics misallocate retention spending to low-margin or high-risk accounts. CLV formulas were updated to incorporate net fee margins and RFM recency weighting rather than raw transaction counts.

Finding 3: Month-over-Month (MoM) Growth & Baseline Stability

- **Original Finding:** Overall quarterly revenue growth demonstrates stable baseline performance across all channels.
- **Validation Method:** Built Power BI DAX time-intelligence models (SAMEPERIODLASTYEAR, DATEADD) and MoM growth queries broken down by month and payment channel.

- **Result:** Aggregated stability masked significant monthly volume fluctuations: volume dipped from ₦172.5M in January ₦160.2M in February before recovering to ₦178.1M in March. The Risk Review Rate peaked concurrently in February at over 20%.
- **Conclusion (Revised): Needs Revision.** Top-line stability creates a false sense of operational security. Dashboard reporting was updated to require granular channel-level and regional MoM variance tracking.

Finding 4: Platform Risk & Fraud Flag Distribution

- **Original Finding:** Compliance risk review flags are uniformly distributed across all customer cohorts and age brackets.
- **Validation Method:** Multi-dimensional SQL joins combining customers onboarding dates with transactions risk flags (risk_review_flag = 'Yes').
- **Result:** The overall risk review rate of 19.60% (2,352 flagged transactions out of 12,000) concentrated disproportionately (>65% of all flags) within digital onboarding cohorts registered in the last 60 days using Web and Mobile rails.
- **Conclusion (Revised): Needs Revision.** Broad, institution-wide fraud controls fail to stop targeted risk vectors. Risk controls were updated to mandate targeted step-up MFA and strict velocity limits for newly onboarded digital cohorts.

Finding 5: Payment Channel Efficiency & Operating Costs

- **Original Finding:** Payment channel efficiency is driven purely by fast processing speeds and low unit transaction costs.
- **Validation Method:** DAX efficiency measures evaluating secondary costs, including transaction reversals (₦15.63M across 326 txns), pending clearing delays (₦9.22M across 188 txns), and support ticket overhead.
- **Result:** Low-cost channels such as USSD and Web incurred high secondary manual review, chargeback, and reconciliation costs that reduced net channel margins despite low initial processing fees.
- **Conclusion (Revised): Needs Revision.** Raw unit cost metrics ignore downstream operational overhead. Evaluation framework shifted to a Risk-Adjusted Channel Efficiency Scorecard factoring in reversal and support costs
